Improve MWPC Tracking Code Efficiency

- We want to know the proton position at the CRV counter.
- Our test beam area has 4 MWPC stations along the beam axis that can be used to track the proton.
- Martin suggested me to improve the tracking code:
 - Martin's code compiles and run on Mu2e Vms using UPS products.
 - Works on my local ubuntu machine (Root 6 and Boost, c++11).
 - We get 45% of total events tracked .
- Suggestion to improve the efficiency:
 - Sten suggested using events with adjacent wires
 - Prof. Craig Dukes suggested using $\frac{3}{4}$ stations

MWPC Introduction

- MWPC= Multiwire Proportional Chamber
- 4 stations
- Each station consists of:
 - 128 vertical wires (for x-position)
 - 128 horizontal wires (for y-position)
 - Each set of wires is read out by 2 TDC boards(modules):
 - More details here:

https://cdcv.sfnal.gov/redmine/projects/ftbfwirechamberdaq/wiki/Processed_hit_data_description

TDC Range

- A good hit is a hit that has a TDC value in the following TDC ranges (shown in red on previous slide) :
 - Modules 1-4: (60 TDC, 90 TDC)
 - Modules 5-8: (50 TDC, 80 TDC)
 - Modules 9-12: (30 TDC, 60 TDC)
 - Modules 13, 15, 16: (60 TDC, 90 TDC)
 - Module 14: (70 TDC, 100 TDC)
- These thresholds were determined by eye. For the run in May and June the TDC range is slightly different. It's in the back-up slides.

Normal Event

- A normal event should have x and y hit on each station. 4 stations, 8 hits.

The left histogram shows the number of wires hit per event. Parsed 19279 events, tracked 8722 events. 45%

The top shows an event display of an event where exactly 8 wires were hit.

Adjacent Hits

- 35% of all events have adjacent wires hit.
- The top shows an event display of an event where 9 wires were hit. Two adjacent wires of station 1 Y axis were hit.
- The bottom left histogram shows the number of wires hit per event.
- The bottom right explain the reason of adjacent wires hit event.

Exaggeration, real beam is perpendicular to the surface of MWPC.

Using Adjacent Hits

- The event has at least one x and one y hit on each station (at least 8 hits total).
- Allow up to 4 adjacent wires.
- Use average position of adjacent wires.
- This method tracks 78% (15,070/19,279) of all events.

Use 3 out of 4 Stations

- Next step, we want to track events with less than 8 hits.
- This shows an event display of an event where 6 wires of 3 stations were hit.

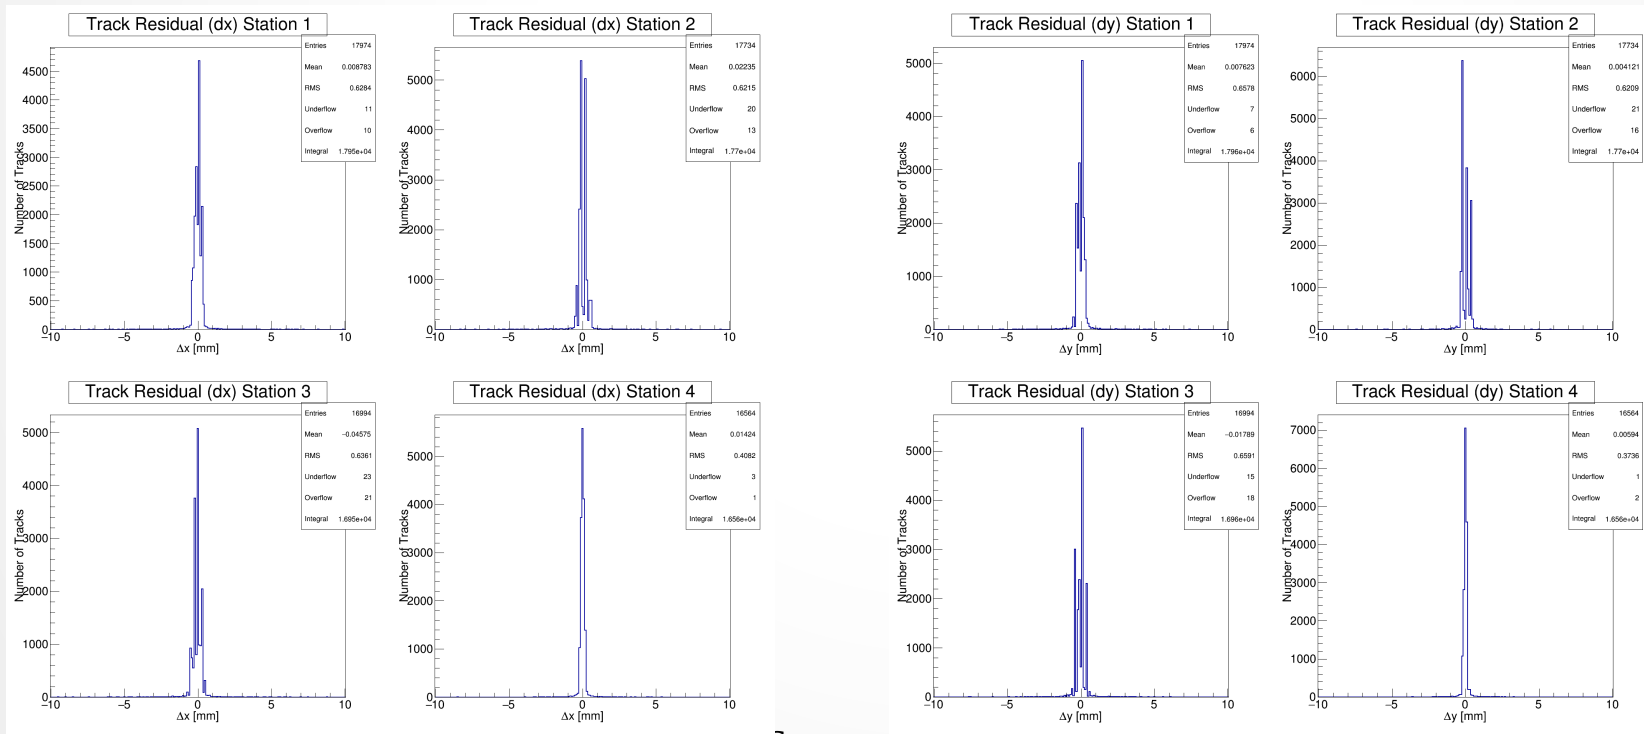

Bad Event

- This shows an event display of a bad event.

Result

- Increased efficiency from 40% to 95% (18,291/19,279).
- Resolution is good
- Left is the track residual for dx, right is the track residual for dy.

Ennao Song

University of Virginia

This is for May run, for June run it is different, in back-up

XY Position Station 1

XY Position Station 2

XY Position Station 3

XY Position Station 4

XY Position at CRV

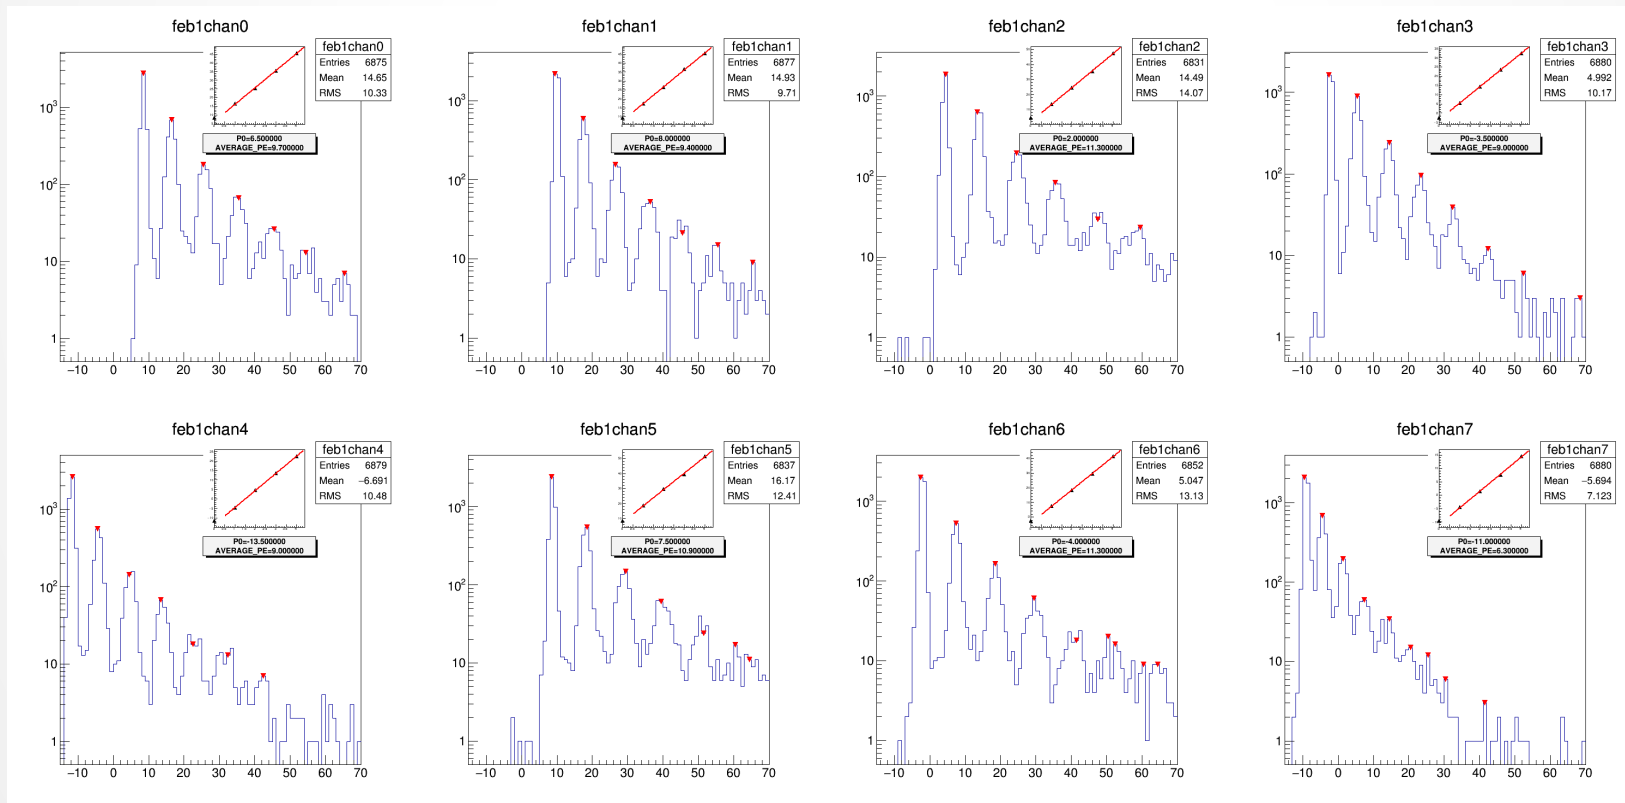

Combine MWPC and CRV Data

- Thanks Martin for merging the MWPC and CRV root file.
- In order for an event to be put into the output tree, it has to have a track from the MWPC, 16 channels from the CRV and meet the following matching criteria :
 - same spill count
 - same event count
 - same number of events in spill
 - time since spill has to be within 2 us of each other

PE calibration

- Calibration of the merged root file for single PE.
- Yongyi told me use the TDC range 0 to 45.

PE distribution

Top edge scan

- Left is 90 deg.(run0171), right is 60 deg.(run0229).

Fiber scan

average_nPE vs Y ,shooting at the fiber, feb 1 channel 3

Gap scan

average_nPE vs Y at the crack, sum of feb 1 channel 5 and feb 1 channel 6

run0176

- Thank you!

Back-up Slides

TDC Range for June

- A good hit is a hit that has a TDC value in the following TDC ranges (shown in red on previous slide) :
 - Modules 1-4: (60 TDC, 90 TDC)
 - Modules 5-8: (50 TDC, 80 TDC)
 - Modules 9-10: (30 TDC, 60 TDC)
 - Modules 11-12: (30 TDC, 70 TDC)
 - Modules 13, 15, 16: (60 TDC, 90 TDC)
 - Module 14: (70 TDC, 100 TDC)

Track Residual (dx) Station 1

Track Residual (dx) Station 2

Track Residual (dx) Station 3

Track Residual (dx) Station 4

Track Residual (dy) Station 1

Track Residual (dy) Station 2

Track Residual (dy) Station 3

Track Residual (dy) Station 4

Track Residual

- The track residual in X is -0.71 mm for station 1, 1.26 mm for station 2, and -0.64 for station 3, so we should adjust the offsets.
- The residuals in the Y direction all still have means within 0.1 mm.

Event Display

- Bottom is an event of 10 hits.

Event Display

- Bottom is an event that is off the center of mwpc.

Event Display

- Bottom shows a proton which is scattered between station 3 and station 4.
